Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

[0001] The present invention relates to an industrial process controller with low-complexity and robust auto-tuning which can be implemented in low power and memory applications, such as a field mounted control unit.

[0002] Field mounted control units include various devices, such as transmitters, actuators, transducers, switches and stand-alone controllers. Field mounted control units are used in process control systems to control the process, measure process variables and to generate outputs representative of the process variables for communication to central controllers or field control elements (e.g. valves) over process control loops. The loops have included two-wire, three-wire and four-wire process control loops. Other loops have also been used, such as optical and radio frequency control loops.

[0003] Field mounted control units are mounted in a field area where current and voltage levels are typically limited to provide intrinsic safety. The units are often powered over the control loop. A separate transducer senses each process variable and provides the sensed variable to a transmitter for transmission to the central controller. Controllers can be located in a central control room or in the field and combine the transducer outputs to generate appropriate control output signals. Control output signals are typically sent over a separate control loop to remote actuators, such as valves, which control the process according to the control output signals. In certain applications, controllers select the most appropriate set of instructions for process control equipment.

[0004] In one application, the transmitter itself includes a control function which provides the control output signals to the remote devices directly, thereby bypassing the central controller. A control function can also be located in the other field control elements, such as valves. This type of control unit is referred to as a "smart" field mounted control unit and is disclosed in more detail in Warrior et al., US-A-5 333 114.

[0005] The control algorithm or equation performed by the controller in the transmitter or in the central control room is specially tailored to the process in which the controller is used. Several basic control algorithms exist, including Proportional (P), Proportional-Integral (PI) Proportional-Derivative (PD) and Proportional-Integral-Derivative (PID) control algorithms. The performance of the control algorithm is determined by control parameters, such as K_p , T_I and T_D which correspond to the proportional gain, integral time and derivative time, respectively, for an ideal-type of PID control algorithm. In some applications, K_p is replaced with a proportional band parameter PB, which is a function of K_p . Other types of PID control algorithms exist, such as parallel and serial equations. These algorithms have corresponding parameters which are similar to the ideal-type parameters. The control parameters are tuned based on a model of the underlying process to operate the process optimally.

[0006] One of the most important tasks in tuning the control parameters is defining the initial process model and estimating the corresponding model parameters. A model for a self-regulating process, such as a temperature, flow or pressure control process, can often be defined by a first order plus dead time equation. A model for a non-self-regulating process, such as a level control process, can be defined by an integrating equation. The corresponding model parameters are estimated by disturbing the process and observing a response in the process variable.

[0007] Several tuning methods are available to tune the control parameters once the process model parameters have been determined. In the Ziegler-Nichols' open-loop tuning method, the process variable $y(t)$ is manually or automatically controlled to a stable state Y_{SS} and a step function is applied to a control signal $u(t)$. The process model parameters are then estimated by observing the response in the process variable. The process model parameter estimation is normally sensitive to the steady state value Y_{SS} . It is difficult to obtain desired closed loop responses if the steady state Y_{SS} is not ideally established before starting the step function.

[0008] In the modified Ziegler-Nichols' frequency domain (closed loop) method, a relay feedback signal is added to a stable state control signal $u(t) = U_{SS}$ and toggled between two values to cause limit cycle oscillations in the process variable from which frequency domain parameters (ultimate period T_U and gain K_U) can be estimated. The control parameters are then generated according to an experimentally based formula. The estimation of frequency parameters T_U and K_U is also sensitive to Y_{SS} . In addition, load and valve friction make tuning difficult and may lead to less than optimized tuned loops. For the purpose of robust and repeatable tuning, a pretuning stage is often needed to have a stable state Y_{SS} before applying the disturbance to the process. The need for pretuning increases the algorithm complexity and the tuning time. The added complexity makes it difficult, if not impossible, to implement such a tuning algorithm in applications having limited power, memory and computational capability, such as in field-mounted control transmitters. These methods and other tuning methods are described in K. Astrom and B. Wittenmark, *Adaptive Control*, Addison-Wesley Publishing, Chapter 8 (1989).

[0009] EP 0 533 498 A1 discloses a PID control device, which identifies a rise characteristic of a controlled system by observing a step response of the system. The PID control device computes PID control parameters based on idle time and slope of the rise characteristic.

[0010] EP 0 097 053 A2 discloses a digital PID process control apparatus, which identifies dynamic characteristics of a process by supplying a persistently exciting signal to a closed-loop control system. The PID control parameters are tuned in accordance with an identified pulse transfer function. A pulse generator is used for superposing a pulse

signal on a set point signal to the process when a model error is detected. A calculator detects a transient change in the model error when the set point signal to the process changes in a pulsed manner.

[0011] The process control system of present invention includes a controller having a process variable input and a control output. The controller generates a control output signal on the control output as a function of a measured process variable received on the process variable input. An auto-tuner is coupled to the controller. The auto-tuner excites the process, estimates a process model based on a rising dead time, a rising rate-of-change, a falling dead time and a falling rate-of-change in the measured process variable and then tunes the function of the controller to the process based on the process model. The auto-tuner obtains robust results, but is computationally simple such that the circuit can be implemented with hardware or software in low-power and low-memory applications, such as in transmitter or valve based field-mounted control units.

[0012] The auto-tuner circuit can be configured to tune the control function for self-regulating processes and for non-self-regulating processes. In one embodiment, the auto-tuner comprises a performance input for receiving a user-defined performance factor. The auto-tuner tunes the control function based on the process model and the performance factor. The performance factor can be selected to provide aggressive, conservative and critically damped performance. The auto-tuner can be used to tune parameters for control functions such as P, PI, PD, PID and various other types of control functions.

[0013] The process control system can also include a trigger circuit which triggers the auto-tuner as a function of a received trigger command, a real time clock output, or an observation of the process.

[0014] In the following preferred embodiments of the present invention will be described in connection with the drawings, in which:

Figure 1 is a diagram of a level control system according to one embodiment of the present invention;

Figure 2 is a block diagram of a transmitter shown in Figure 1, which includes a control unit;

Figure 3 is a diagram of a process control system of the present invention;

Figure 4 is a waveform diagram illustrating an auto-tuning stage and a closed loop control stage for a non-self-regulating process, according to the present invention;

Figure 5 is a waveform diagram illustrating an auto-tuning stage for a self-regulating process; and

Figure 6 is a block diagram of a valve having a control unit according to the present invention.

[0015] The present invention is a process control system having a robust auto-tuning feature which is computationally simple such that the system can be implemented in a low-power field-mounted control unit in a process control system.

[0016] Figure 1 is a diagram of one embodiment in which the process control system of the present invention is useful. The process control system includes master controller 10, transmitter 12, tank 14, input valve 16 and output valve 18. Master controller 10 is coupled to transmitter 12 and input valve 16 through two-wire process control loop 20. Loop 20 can include a 4-20 mA or a 10-50 mA current loop, for example, which allows master controller 10, transmitter 12 and valve 16 to communicate with one another by varying the current level through the loop. In an alternative embodiment, master controller 10, transmitter 12 and valve 16 communicate by varying the voltage level on loop 20. Concurrently, master controller 10 and transmitter 12 communicate digitally over loop 20 in a carrier modulated fashion, such as in the HART® protocol.

[0017] Other digital communication systems can be used, including a Fieldbus Standard which is presently being adopted by the Fieldbus Foundation. Alternatively, loop 20 carries baseband modulated digital signals such as DE protocol. In addition, master controller 10 and transmitter 12 can communicate with one another optically over single or dual optical fibers or by radio frequency. An example of an optical control circuit is disclosed in U.S. Patent No. 5,258,868, which is hereby incorporated by reference.

[0018] Master controller 10 includes a controller 22 and a power source 23 which provide power and control to loop 20. Master controller 10 can be positioned in a central control room or in a remote, field location with transmitter 12. Master controller 10, transmitter 12 and valve 16 can be coupled to one another in a variety of configurations as discussed in more detail in Warrior et al., U.S. Patent No. 5,333,114.

[0019] In the embodiment shown in Figure 1, the magnitude of current flowing through loop 12 represents a control output $u(t)$ which controls flow into tank 14 by controlling the position of valve 16. Transmitter 12 preferably includes its own control function which is capable of taking over the operation of loop 20 from master controller 10 and sinking a variable amount of current to adjust control output $u(t)$. The position of valve 18 controls the flow out of tank 14. Valve 18 is adjusted by a valve control signal $o(t)$ which is provided by a transmitter 26 over a two-wire process control loop 28 which can be coupled to loop 20 in parallel (as shown in phantom) with loop 20 in a cascade fashion. The parallel configuration is referred to as a multidrop configuration. The valve control signal $o(t)$ can also be provided by a separate loop which is coupled to transmitter 12 or master controller 10.

[0020] A sensor 24 is coupled to tank 14 for measuring a level $y(t)$ of fluid in the tank. The rate-of-change in level $dy(t)/dt$ is a function of the positions of valves 16 and 18. Control output $u(t)$ has a "direct action" on the process variable

$y(t)$ since an increase in $u(t)$ causes an increase in $y(t)$. The signal $o(t)$ has a "reverse action" on the process variable $y(t)$ since an increase in $o(t)$ causes a decrease in $y(t)$. Sensor 24 can include any suitable sensor, such as an absolute or differential pressure sensor, an ultrasonic sensor or a microwave sensor. Other types of sensors capable of generating a signal representative of the level of fluid in tank 14 can also be used. The level control system shown in Figure 1 is one example of a non-self-regulating process. The present invention can also be used with self-regulating processes and with other non-self-regulating processes.

[0021] Figure 2 is a block diagram of transmitter 12 according to a first preferred embodiment of the present invention. Transmitter 12 is a "smart" transmitter in that it has computing capability, such as that performed by a microprocessor. Transmitter 12 includes a rugged, explosion proof housing 34 for mounting in the field, input terminal 36, output terminal 38, input-output circuit 40, demodulator 42, digital-to-analog (D/A) converter 44, modulator 46, microprocessor 48, analog-to-digital (A/D) converter 50, process variable sensor 52, clock circuit 54 and memory 56. Clock circuit 54 is connected to microprocessor 48 to sequence the operation of the microprocessor.

[0022] Input terminal 36 is coupled to master controller 10 (shown in Figure 1) while output terminal 38 is coupled to valve 16 (also shown in Figure 1). Input-output circuit 40 is coupled between input terminal 36 and output terminal 38. Circuit 40 includes input filter circuit 70, voltage regulator 72, current sink 74 and current sink 76 which are connected in series with one another in loop 20. Input-output circuit 40 receives process signals from loop 20 at input terminal 36 and supplies control output signals $u(t)$ at output terminal 38 as a function of the process signals. Voltage regulator 72 within input-output circuit 40 receives power from loop 20 and provides a regulated voltage for powering all the various elements of transmitter 12.

[0023] The process signals used in generating control output $u(t)$ comprise setpoints representative of a desired process state, process variables produced by the process, commands and whole or partial instruction sets for operating microprocessor 48, coefficients of terms for controlling microprocessor 48 and status requests from master controller 10. Input filter circuit 70 receives the process signals and directs the signals to demodulator 42. Demodulator 42 demodulates modulated process signals from the current loop and provides corresponding digital information to microprocessor 48. The information can be stored in memory 56 if desired.

[0024] Microprocessor 48 also receives process signals from process variable sensor 52. Sensor 52 measures a process variable $y(t)$, such as a level as shown in Figure 1, and provides the measurement to A/D converter 50 which digitizes the measurement for microprocessor 48. The process variable measurements can then be stored in memory 56 for analysis or transmitted back to master controller 10 over loop 20. Microprocessor 48 transmits digital information to master controller 10 through modulator 46 and current sink 76, which modulate the information onto loop 20. In an alternative embodiment, sensor 52 and A/D converter 50 are located external to transmitter 12. In this embodiment, the process variable measured by sensor 52 is communicated to microprocessor 48 over loop 20 along with other process variables from different sensors.

[0025] Current sink 74 adjusts control output $u(t)$ by adjusting the level of current flowing through loop 20. Microprocessor 48 operates current sink 74 through D/A converter 44 based on a control algorithm or software routine stored in memory 56 and as a function of the measured process variable $y(t)$, stored control parameters and instructions received from master controller 10. For example, master controller 10 may provide a set point Y_{SET} or other command to microprocessor 48 which instructs the microprocessor to adjust control output $u(t)$ such that the process variable $y(t)$ approaches the set point Y_{SET} .

[0026] According to the present invention, memory 56 also includes an auto-tuning algorithm or software routine which tunes the control parameters used by the control algorithm to match the process being controlled. The auto-tuning algorithm causes microprocessor 48 to adjust control output $u(t)$ over time and observe a response in the process variable $y(t)$. From this response, microprocessor 48 can estimate model parameters for the process and use the model parameters to calculate the desired control parameters.

[0027] The communication methods and transmitter connections discussed with reference to Figure 2 are provided as examples only. Other configurations can also be used, such as those described in U.S. Patent No. 5,333,114.

AUTO-TUNING

[0028] Figure 3 is an illustration of the auto-tuning and control functions performed by microprocessor 48 according to one embodiment of the present invention. Control system 100 includes summing junction 102, PID controller 104, tuning circuit 106, switching junction 108 and process 110. For a "direct action" control output, a process variable setpoint Y_{SET} is provided to a positive input of summing junction 102 and the measured process variable $y(t)$ is provided to a negative input of summing junction 102. For a "reverse action" control output (not shown), Y_{SET} is provided to a negative input of summing junction 102 and $y(t)$ is provided to a positive input of summing junction 102. The output of summing junction 102 generates an error signal $e(t)$ which represents the difference between the setpoint Y_{SET} and the measured process variable $y(t)$. Error signal $e(t)$ is provided to PID controller 104. PID controller 104 includes a proportional gain block 112, an integrating block 114 and a derivative block 116. In an alternative embodiment (not

shown), the measured process variable $y(t)$ is provided directly to derivative block 116, as opposed to through summing junction 102. The outputs of blocks 112, 114 and 116 are provided to positive inputs of summing junction 118. During closed loop control, the output of summing junction 118 provides the control output $u(t)$ to control process 110. The basic function of PID controller 104 is defined by Equation 1:

$$u(t) = K_P e(t) + \frac{K_P}{T_I} \int e(t) dt + K_P T_D \frac{de(t)}{dt} \quad \text{Eq. 1}$$

where K_P , T_I and T_D are tuned control parameters that determine the performance of PID controller 104. The control parameters are tuned, or modified according to the present invention to match the characteristics of process 110 at a commissioning stage or at any point during control of the process.

[0029] Tuning circuit 106 includes tuning control circuit 122, excitation circuit 124, process model estimation circuit 126 and control parameter rule circuit 128. Tuning control circuit 122 is coupled to excitation circuit 124, process model estimation circuit 126 and control parameter rule circuit 128 to control the overall function of tuning circuit 106. Excitation circuit 124 provides an open loop excitation signal, which varies over time, to process 110 through switching junction 108. The excitation signal is used as the control output signal during an open loop auto-tuning stage. Switching junction 108 can be an actual switch or can be a transfer of control from one algorithm or software routine to the next. Model estimation circuit 126 then observes the response in the measured process variable $y(t)$ and generates a model of process 110, as is described in greater detail below. This model is provided to control parameter rule circuit 128 for tuning the control parameters for PID controller 104 based on a selected set of tuning rules. The process model and tuned control parameters are then stored in memory 56 (Figure 2) and can be provided to master controller 10 over process control loop 36 to optimize the supervisory or cascade control of the process. The process model can be provided to other cascade connected devices for use in additional tuning procedures.

[0030] Tuning circuit 106 further includes a trigger circuit 134, a tuning alert circuit 136 and a real time clock 138 which are coupled to, or could be incorporated in, tuning control circuit 122. Trigger circuit 134 triggers tuning control circuit 122 to perform the auto-tuning function of the present invention based on trigger signals supplied by trigger input 140, tuning alert circuit 136 or real time clock circuit 138. Trigger input 140 is supplied by microprocessor 48 (Figure 2) in response to commands provided by master controller 10 over process control loop 36. The commands may be initiated on demand by the user or at the request of master controller 10. Alternatively, real time clock 138 may trigger the auto-tuning function based on a selected time period, such as every halfhour. In an alternative embodiment, real time clock 138 is incorporated in master controller 10 and supplies the trigger signal to trigger input 140 over process control loop 36.

[0031] Tuning alert circuit 136 triggers the auto-tuning function through a trigger output 142. During the closed loop control stage, tuning control circuit 122 observes $e(t)$, $u(t)$ and $y(t)$ and passively calculates new control parameters through circuits 126 and 128. Tuning alert circuit 136 compares the new calculations with the previously stored operating process control parameters. If the difference between the calculations is greater than a specified range, tuning alert circuit 136 triggers the auto-tuning function through trigger circuit 134 or notifies the user or master controller 10 through alert output 144. Tuning alert circuit 136 also passively verifies the estimated process model with the process by fitting current values of $y(t)$ and $u(t)$ into the model equation (discussed below) to see if the model is correct. If not, circuit 136 triggers the auto-tuning function or issues an alert on output 144. Circuit 136 also monitors $e(t)$ and $y(t)$ after a set point change or a major disturbance in the process and issues an alert if the desired performance (e.g. critically damped) is not present. For example, the integral of the square of the error signal $e(t)$ or the integral of the absolute value of the error can be compared with a threshold value stored in memory 56. If the error integral exceeds the threshold, circuit 136 issues an alert. In addition, circuit 136 monitors $y(t)$ during the tuning stage. If $y(t)$ is not responding or responds incorrectly, circuit 136 generates a tuning failure alert on output 144. The user can take action to correct the auto-tuning function, such as by changing the selected values of U_{MIN} , U_{MAX} or a performance factor α described below.

[0032] Figure 4 is a diagram illustrating the waveforms of control output $u(t)$ and process variable $y(t)$. Once the auto-tuning stage has been initiated, tuning control circuit 122 monitors the sign of $e(t)$ to determine whether $y(t)$ is above or below Y_{SET} . If $e(t)$ is negative, $y(t)$ is above Y_{SET} . The control loop is opened at switching junction 108 and excitation circuit 124 forces $u(t)$ to a user-selected minimum control output value U_{MIN} at time t_0 to force $y(t)$ toward Y_{SET} . Tuning control circuit 122 then monitors $e(t)$. Once $e(t)$ is below a selected threshold error level, excitation circuit 124 applies a user-selected maximum control output value U_{MAX} to process 110, at time t_R , such that $y(t)$ starts increasing. At time t_{MAX} , $y(t)$ is maximally increasing. At time t_F , the minimum control output value U_{MIN} is again applied to process 110 such that $y(t)$ starts decreasing. At time t_{LMAX} , $y(t)$ is maximally decreasing. At time t_A , the auto-tuning stage ends and process control system 100 becomes a closed PID control loop which adjusts $u(t)$ to bring the process variable to the set point $y(t) = Y_{SET}$.

[0033] If the sign of $e(t)$ were positive at time t_0 , then the excitation waveform $u(t)$ shown in Figure 4 would simply

be inverted. Excitation circuit 124 would apply $u(t) = U_{MAX}$ such that $y(t)$ rises toward Y_{SET} , then $u(t) = U_{MIN}$ such that $y(t)$ falls and then $u(t) = U_{MAX}$ such that $y(t)$ rises again.

[0034] By varying the control output $u(t)$ over time during the auto-tuning stage, tuning circuit 106 has the ability to estimate all system parameters accurately with repeatable and robust results such that PID controller 104 provides the desired performance. Tuning circuit 106 can be configured to estimate the process model parameters for non-self-regulating and self-regulating processes according to the present invention.

1. Non-Self-Regulating Processes

[0035] The level process shown in Figure 1 is one example of a non-self-regulating process. A non-self-regulating process is a process in which the measured process variable $y(t)$ will continue to increase or decrease as long as the control signal $u(t)$ is not equal to a steady state value U_{SS} (i.e., when the inlet and outlet flows are not equal in a level process). The level balance equation of the level process shown in Figure 1 can be written as:

$$\frac{dy(t)}{dt} = m_1 u(t-L) - m_2 O(t) \tag{Eq. 2}$$

Equation 2 assumes that valves 16 and 18 are linear and neglects a head pressure effect on the valves. L is the system dead time and m_1 and m_2 are constants corresponding to the volume flow into and out of tank 14 divided by the area of tank 14.

[0036] When control output $u(t)$ is at a steady state, U_{SS} , and the dead time effect disappears,

$$\frac{dy(t)}{dt} = 0 = m_1 U_{SS} - m_2 O(t) \tag{Eq. 3}$$

[0037] When $y(t)$ is maximally increasing (see Figure 4), $u(t) = U_{MAX}$ and,

$$R_R = \left. \frac{dy(t)}{dt} \right|_{MAX} = m_1 U_{MAX} - m_2 O(t) = m_1 (U_{MAX} - U_{SS}) \tag{Eq. 4}$$

[0038] Similarly, when $y(t)$ is maximally decreasing (see Figure 4), $u(t) = U_{MIN}$ and,

$$R_F = \left. \frac{dy(t)}{dt} \right|_{-MAX} = -(m_1 U_{MIN} - m_2 O(t)) = m_1 (U_{SS} - U_{MIN}) \tag{Eq. 5}$$

[0039] By dividing Equation 4 by Equation 5, the following mathematical relationship can be derived:

$$\frac{R_R}{R_F} = \frac{U_{MAX} - U_{SS}}{U_{SS} - U_{MIN}} \tag{Eq. 6}$$

[0040] A rising dead time L_R and a falling dead time L_F (see Figure 4) of process variable $y(t)$ can be written as:

$$L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_R}$$

$$L_F = t_{MAX} - t_F - \frac{y(t_{MAX}) - y_{MAX}}{-R_F} \tag{Eqs. 7-8}$$

where $y(t_{MAX})$ is the process variable at time t_{MAX} when the time derivative of $y(t)$ reaches the maximum in the positive direction. Similarly, $y(t_{MAX})$ is the process variable at time t_{MAX} when the time derivative of $y(t)$ reaches the maximum in the negative direction. The term y_{MIN} is the minimum value of $y(t)$ between times t_R and t_F and the term y_{MAX} is the maximum value of $y(t)$ between times t_F and time t_A . Through Equations 4-5 and 7-8, process model estimation circuit

126 calculates L_R , L_F , R_R and R_F .

[0041] From Equations 4-5 and 6-8, the process model parameters U_{EST} (estimated steady state U_{SS}), m_1 and L can be estimated as:

$$U_{EST} = \frac{R_R U_{MIN} + R_F U_{MAX}}{R_R + R_F}$$

$$m_1 = \frac{R_R}{U_{MAX} - U_{EST}} = \frac{R_F}{U_{EST} - U_{MIN}} = \frac{R_R + R_F}{U_{MAX} - U_{MIN}}$$

$$L = \max(L_R, L_F) \quad \text{Eqs. 9-11}$$

[0042] To allow the resulting PID function to compensate for the worst case, the overall system dead time L is estimated in Equation 11 as the maximum of L_R and L_F . Process model estimation circuit 126 estimates the process model parameters U_{EST} , m_1 and L according to Equations 9-11. Equations 9-11 can easily be modified to estimate a process in which the system is reverse acting by exchanging U_{MAX} and U_{MIN} . The process model parameters are provided to control parameter rule circuit 128 which tunes the control parameters K_P , T_I and T_D according to selected rules, as discussed in greater detail below.

[0043] The unfiltered process variable $y(t)$ may be too noisy to produce repeatable tuning parameters. Although there are several suitable methods to handle a noisy process variable, the present invention preferably includes a low pass filter 130 (also referred to as a dynamic filter or a user damping filter) coupled to the output of process 110. With low pass filter 130, process model estimation circuit 126 can provide robust estimation of model parameters U_{EST} , m_1 and L by using Equations 9-11.

[0044] In an alternative embodiment, Equations 4-5 and 7-8 are replaced with the following equations to improve noise reduction and obtain even more reliable results. The rising rate of change R_R in the process variable can be defined over a sampling period T as:

$$R_{R1} = m_1(U_{MAX} - U_{SS}), \text{ where } R_{R1} = \frac{dy(t)}{dt} \text{ at } t = t_{MAX}$$

$$R_{R2} = m_1(U_{MAX} - U_{SS}), \text{ where } R_{R2} = \frac{dy(t)}{dt} \text{ at } t = t_{MAX} + T$$

...

$$R_{RN} = m_1(U_{MAX} - U_{SS}), \text{ where } R_{RN} = \frac{dy(t)}{dt} \text{ at } t = t_{MAX} + (N-1) T \quad \text{Eq. 12}$$

[0045] Since all the R_R 's in Equation 12 correspond to the same control signal U_{MAX} , the R_R 's can be averaged according to the following mathematical expression for a better approximation of R_R in order to minimize a least square error in estimating the constant m_1 :

$$R_R = \frac{\sum_{n=1}^N R_{Rn}}{N} \quad \text{Eq. 13}$$

[0046] Similarly, the following equation can be used for the falling direction:

$$R_F = \frac{\sum_{n=1}^N R_{Fn}}{N} \quad \text{Eq. 14}$$

The rising and falling dead times L_R and L_F are estimated according to Equations 7-8.

[0047] Control parameter rule circuit 128 tunes the control parameters for PID controller 104 according to a selected set of rules. Although any suitable set of rules can be used according to the present invention, circuit 128 preferably includes internal model-based control (IMC) tuning rules. With Equations 9-11, the process model parameters can be

estimated with very low computational complexity. With IMC tuning rules, the corresponding control parameters for PID controllers can be derived from:

$$K_p = \frac{2\tau + L}{m_1(\tau + L/2)^2}$$

$$T_i = 2\tau + L$$

$$T_D = \frac{\tau L + L^2/4}{2\tau + L} \quad \text{Eqs. 15-17}$$

where K_p , T_i and T_D are the proportional gain, integral time and derivative time, respectively, of PID controller 104, and τ is a desired closed loop response time constant. The control parameters for P, PI and PD controllers are slightly different from those in Equations 15 and 16 and can be found in Internal Model Control, PID Controller Design, 25 Ind. Eng. Chem. Process Des. Dev. 252-65 (1986). According to the present invention, the time constant τ is defined as a function of a performance factor α , where

$$\tau = \alpha L \quad \text{Eq. 18}$$

[0048] The performance factor α preferably ranges between 1/2 and 3 to cover the degrees of desired performance. For example, $\alpha=1$ generates a critical damped closed loop response. A smaller α generates a more aggressive, faster response and a larger α generates a more conservative, slower response. Inserting Equation 21 into Equations 18-20, the corresponding PID tuned control parameters become:

$$K_p = \frac{4}{m_1 T_i}$$

$$T_i = (2\alpha + 1) L$$

$$T_D = \frac{\alpha + 1/4}{2\alpha + 1} L \quad \text{Eqs. 19-21}$$

The PID tuned control parameters K_p , T_i and T_D can therefore be calculated by control parameter rule circuit 128 with low computational complexity. The performance factor α is provided to circuit 128 through an input 132 and control circuit 122. In the embodiment shown in Figure 2, the performance factor α is provided to microprocessor 48 by master controller 10 as a digital value modulated on loop 20.

[0049] In an alternative embodiment, process model estimation circuit 126 and control parameter rule circuit 128 are combined and the control parameters are calculated directly as a function of L_R , L_F , R_R , and R_F . The process model parameter equations are folded into the control parameter equations such that separate calculations of the process model parameters are unnecessary.

[0050] In the previous discussion, it has been assumed that the process is linear. For a non-linear process, such as a process with non-linear valve characteristics and head pressure effects on the valve, the actual stable state valve position during normal closed loop control at the end of time sequence t_A can be used to replace the estimated value U_{EST} in Equations 10 and 15 for a more reliable performance.

2. Self-Regulating Processes

[0051] Process model estimation circuit 126 (shown in Figure 3) can also be configured for estimating the process model parameters for a self-regulating process such as heat exchanger temperature, flow and pressure control processes. Most self-regulated processes can be modeled by the following first order plus dead time equation:

$$T_c \frac{dy(t)}{dt} + y(t) = K_S u(t-L) \quad \text{Eq. 22}$$

where process model parameters L , T_c and K_S represent the dead time, time constant and static gain of the process, respectively.

[0052] The process model parameters are estimated by applying the open loop control pattern $u(t)$ that is shown in Figure 5. As in the non-self-regulating process, the auto-tuning circuit of the present invention separates the process model parameters in the rising and falling directions to model the worst case performance. Considering the rising direction when $u(t) = U_{MAX}$ and $y(t)$ is increasing ($dy(t)/dt > 0$) and assuming the dead time L has passed, the following equations can be written from time t_{MAX} to time t_f :

$$\begin{aligned} T_R R_{R1} + y_1 &= K_R U_{MAX} \\ T_R R_{R2} + y_2 &= K_R U_{MAX} \\ &\dots \\ T_R R_{RN} + y_N &= K_R U_{MAX} \end{aligned} \quad \text{Eq. 23}$$

where T_R and K_R are the time constant and static process gain in the rising direction and N is the number of samples of $y(t)$ in the rising direction. R_{Rn} is the rate of change of $y(t)$ at an n th sample after t_{MAX} , which is defined as:

$$R_{Rn} = \frac{dy(t)}{dt} \text{ at } t = t_{MAX} + (n-1)T \quad \text{Eq. 24}$$

where T is the sample period. The matrix form of the above equation can be written as:

$$\begin{bmatrix} R_{R1} - U_{MAX} \\ \dots \\ R_{RN} - U_{MAX} \end{bmatrix} \begin{bmatrix} T_R \\ K_R \end{bmatrix} = \begin{bmatrix} -y_1 \\ \dots \\ -y_N \end{bmatrix} \quad \text{Eq. 25}$$

[0053] This equation can be solved to estimate T_R and K_R while minimizing the least square error by using the pseudo inverse of the matrix on the left-hand side of Equation 25. This can be done by modifying the above equation by Equation 26:

$$\begin{bmatrix} R_{R1} & \dots & R_{RN} \\ -U_{MAX} & \dots & -U_{MAX} \end{bmatrix} \quad \text{Eq. 26}$$

which results in:

$$\begin{bmatrix} \sum_{n=1}^N R_{Rn}^2 & -U_{MAX} \sum_{n=1}^N R_{Rn} \\ -U_{MAX} \sum_{n=1}^N R_{Rn} & NU_{MAX}^2 \end{bmatrix} \begin{bmatrix} T_R \\ K_R \end{bmatrix} = \begin{bmatrix} -\sum_{n=1}^N R_{Rn} y_n \\ U_{MAX} \sum_{n=1}^N y_n \end{bmatrix} \quad \text{Eq. 27}$$

[0054] From Equation 27, the following estimations can be derived :

$$\begin{bmatrix} T_R \\ K_R \end{bmatrix} = \frac{1}{U_{MAX} (N \sum R_{Rn}^2 - (\sum R_{Rn})^2)} \begin{bmatrix} -NU_{MAX} \sum y_n R_{Rn} + U_{MAX} (\sum R_{Rn}) (\sum y_n) \\ (-\sum R_{Rn}) (\sum R_{Rn} y_n) + (\sum R_{Rn}^2) (\sum y_n) \end{bmatrix} \quad \text{Eq. 28}$$

[0055] The same method can be used to derive the rising system dead time L_R as was used for the non-self-regulating process:

$$L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_{R1}} \quad \text{Eq. 29}$$

5 where R_{R1} is the rising rate-of-change of $y(t)$ at sample $n=1$.

[0056] In the falling direction, $u(t) = U_{MIN}$ and $y(t)$ is decreasing ($dy(t) < 0$). Similar equations can be used to estimate time constant T_F , static gain K_F and dead time L_F for the falling direction, as shown below:

$$\begin{bmatrix} T_F \\ K_F \end{bmatrix} = \frac{1}{U_{MIN} \left(N \sum R_{Fn}^2 - \left(\sum R_{Fn} \right)^2 \right)} \begin{bmatrix} -NU_{MIN} \sum y_n R_{Fn} + U_{MIN} \left(\sum R_{Fn} \right) \left(\sum y_n \right) \\ \left(- \sum R_{Fn} \right) \left(\sum R_{Fn} y_n \right) + \left(\sum R_{Fn}^2 \right) \left(\sum y_n \right) \end{bmatrix}$$

$$L_F = t_{-MAX} - t_F - \frac{y(t_{-MAX}) - y_{MAX}}{R_{F1}}$$

Eqs. 30-31

where R_{F1} is the falling rate-of-change of $y(t)$ at sample $n=1$.

20 [0057] During operation, from time t_R to time t_F , process model estimation circuit 126 (Figure 3) estimates L_R according to Equation 32 and counts the variables ΣR_{Rn} , ΣR_{Rn}^2 , Σy_n and $\Sigma y_n R_{Rn}$ in Equation 28. From time t_F to time t_A , circuit 126 estimates L_F according to Equation 34 and counts the variables ΣR_{Fn} , ΣR_{Fn}^2 , Σy_n and $\Sigma y_n R_{Fn}$ in Equation 33.

[0058] A typical process behaves differently in the rising and falling directions. For example, in temperature control applications, the process may exhibit this behavior because of endothermic and exothermic reactions in the process. Arbitrarily choosing the process model parameters in either the rising or falling direction can sometimes lead to an undesirable closed loop control performance. The process model estimation circuit of the present invention obtains a more robust PID control performance. First, a strong low-pass filter (filter 130) is used to prevent noise from corrupting the derivative signal $dy(t)/dt$. Second, the process model parameters are estimated by circuit 126 according to the following equations:

$$K_S = \max(K_R, K_F)$$

$$T_C = \min(T_R, T_F)$$

$$L = \max(L_R, L_F)$$

Eqs. 32-34

[0059] Once the process model parameters have been estimated for the first order plus dead time process equation, the P, I and D control parameters can be tuned as a function of several existing tuning rules. For example, the following Internal Model Control (IMC) tuning rules have been found to give preferred PID control performance:

$$K_p = \frac{2T_c + L}{K_s(2\tau + L)}$$

$$T_i = T_c + \frac{L}{2}$$

$$T_d = \frac{T_c L}{2T_c + L}$$

Eqs. 35-37

where K_p , T_i and T_d are the proportional gain, integral time and derivative time, respectively. As with the non-self-regulating process, the closed loop time constant τ is defined as a function of the performance factor α , where

$$\tau = \alpha L$$

Eq. 38

As discussed above, the performance factor α preferably ranges between 1/2 and 3. Equation 34 ensures a maximum closed loop time constant τ . Equations 32 and 33 ensure the smallest possible proportional gain K_p for a given per-

formance factor α .

[0060] The auto-tuning circuit of the present invention can also be implemented in a valve control unit, for example. Figure 6 is similar to Figure 2 and is a block diagram of a valve control unit 160 which includes input filter circuit 162, voltage regulator 164, adjustable current sink 166, current transducer 168, demodulator 170, A/D converter 172, modulator 174, microprocessor 176, memory 178, clock circuit 180, D/A converter 182 and actuator 184. Circuit 162, regulator 164, and current transducer 168 are connected in series with process control loop 186 for receiving the measured process variable $y(t)$ and modulated digital data, such as a set point Y_{SET} , from the loop.

[0061] Demodulator 170 demodulates the data and provides the data to microprocessor 176 for analysis. Regulator 164 receives power from loop 186 and provides a regulated voltage for powering the elements of valve control unit 160. Current transducer 168 measures the analog current level $y(t)$ in loop 186, which is converted by A/D converter 172 into digital data for microprocessor 176. Microprocessor 176 transmits data over loop 186 by modulating the current through sink 166 with modulator 174, such as by the HART® protocol. The auto-tuning algorithm, control algorithm, process model and tuning parameters are stored in memory 178 for configuring microprocessor 176 to control actuator 184 through D/A converter 182 as a function of the measured process variable $y(t)$ and the set point Y_{SET} .

[0062] The auto-tuning circuit of the present invention has several advantages that are not present in existing tuning techniques. The auto-tuning circuit generates accurate model parameters with only simple calculations. The simple calculations allow the auto-tuning circuit to be implemented in low-power and low-memory applications, such as in field-mounted control units. A 4-20 mA current loop provides only a few milli-Amps after the signal range is subtracted to power all of the electronic components in the unit. This limits the complexity of the components and the memory space. A typical memory in a transmitter may be limited to 8K to 64K bytes, for example.

[0063] The auto-tuning circuit of the present invention does not require much user interaction. Unlike the Ziegler-Nichols' open loop test, the auto-tuning circuit of the present invention does not require users to establish a stable state before the open loop test is run and instead has an ability to assess the stable state conditions. The user sets up the tuning procedure by providing initial variables such as desired U_{MAX} and U_{MIN} levels, selects a desired performance factor α and then initiates the auto-tuning procedure.

[0064] The auto-tuning circuit of the present invention can be implemented as a manual operation or an automatic operation, and it can be operated in the loop commissioning stage at system initialization, or at any other time the user wishes to tune the loop. For automatic operation, the auto-tuning circuit is capable of bringing the process variable close to the set point and starting the tuning exercise automatically without the user's involvement. With manual operation, the user brings the process variable close to the set point and then initiates tuning through master controller 10.

[0065] The auto-tuning circuit of the present invention generates a guided disturbance of the process. Unlike closed loop relay control based tuning or other frequency domain techniques, the present invention can be restricted to operate within a defined zone. For example, some users may prefer a $u(t)$ disturbance of only 10% and 75% of the full scale. The auto-tuning circuit is simple, user friendly, repeatable and robust. It can be used to tune control parameters for P, PI, PD, PID and other types of controllers such as fuzzy logic controllers. Suitable fuzzy logic controllers are described in the article "Auto-Tuned Fuzzy Logic Control," by J. Quin, ACC Conference 1994, Baltimore Maryland, which is hereby incorporated by reference.

[0066] Although the present invention has been described with reference to preferred embodiments, workers skilled in the art will recognize that changes may be made in form and detail without departing from the scope of the invention as defined in the claims. The tuning circuit can be implemented as a software routine or algorithm stored in memory for execution by a programmed computer, such as a microprocessor. In alternative embodiments, the circuit is implemented in digital or analog hardware. The tuning circuit can be located in the transmitter, in the valve or in master controller 10. Master controller 10 can be located in a central control room, at a remote location near the transmitter or valve or in a hand-held configurator which is used to configure the transmitter during the commissioning stage. The tuning circuit can estimate the process model parameters and tune the control parameters in different calculation stages or can fold the process model parameter equations into the control parameter equations such that there is only one calculation stage. Other configurations can also be used according to the present invention.

Claims

1. A process control apparatus (100) for controlling a process (110) through a control output signal ($u(t)$) as a function of a measured process variable ($y(t)$) comprising:

control means (104) having a process variable input and a control output, wherein the control means generates the control output signal ($u(t)$) on the control output in response to the measured process variable ($y(t)$) received on the process variable input and based on control function parameters; and
tuning means (106) comprising:

excitation means (124) having an excitation output coupled to the control output for generating an excitation signal which rises and falls over time; characterized in that the tuning means (106) further comprises:

estimating means (126) for calculating a rise dead time L_R , a fall dead time L_F , a rising rate-of-change R_R and a falling rate-of-change R_F in the measured process variable $y(t)$ in response to the excitation signal and for estimating a process model based on L_R , L_F , R_R and R_F ; and
parameter calculating means (128) coupled to the estimating means (126) for calculating the control function parameters based on the process model.

2. The process control apparatus (100) of claim 1, wherein the estimating means (126) comprises means for calculating R_R and R_F according to the mathematical expressions:

$$R_R = \frac{\sum_{n=1}^N R_{Rn}}{N}$$

$$R_F = \frac{\sum_{n=1}^N R_{Fn}}{N}$$

where N is a selected number of samples of the measured process variable $y(t)$ in the rising and falling directions and R_{Rn} and R_{Fn} are the rising and falling rates-of-change of the measured process variable $y(t)$ at the nth sample.

3. The process control apparatus (100) of claim 1 or 2, wherein the estimating means (126) comprises:

means for incrementing the excitation output signal from a selected minimum value U_{MIN} to a selected maximum value U_{MAX} and for decrementing the excitation signal from U_{MAX} to U_{MIN} ; and
means for calculating L_R and L_F according to the mathematical expressions:

$$L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_R}$$

$$L_F = t_{MAX} - t_F - \frac{y(t_{MAX}) - y_{MAX}}{-R_F}$$

where t_{MAX} and t_{MAX} are times at which the measured process variable $y(t)$ is maximally increasing and decreasing, respectively, t_R and t_F are times at which U_{MAX} and U_{MIN} are applied to the excitation output, respectively, $y(t_{MAX})$ and $y(t_{MAX})$ are values of the measured process variable $y(t)$ at times t_{MAX} and t_{MAX} , respectively, y_{MIN} is the minimum measured process variable between times t_R and t_F , and y_{MAX} is the maximum measured process variable between times t_F and t_A , where t_A is a time at which U_{MIN} is removed.

4. The process control apparatus (100) of any of claims 1 to 3, wherein the process model includes a process dead time value L and the estimating means (126) estimates L as the maximum of L_R and L_F .
5. The process control apparatus (100) of any of claims 1 to 4, wherein the excitation means (124) comprises:
means for incrementing the excitation signal from a selected minimum value U_{MIN} to a selected maximum value U_{MAX} and for decrementing the excitation signal from U_{MAX} to U_{MIN} .
6. The process control apparatus (100) of claim 5, wherein the apparatus (100) is configured for controlling a non-self-regulated process in which the process model parameters include a constant m_1 and the estimating means (126) comprises means for estimating m_1 according to the mathematical expression:

$$m_1 = \frac{R_R + R_F}{U_{MAX} - U_{MIN}}$$

- 5 7. The process control apparatus (100) of claim 5 wherein the apparatus (100) is configured for controlling a non-self-regulated process in which the process model parameters include an estimated steady state value U_{EST} of the control output signal and the estimating means (126) comprises means for estimating U_{EST} according to the mathematical expression:

$$10 \quad U_{EST} = \frac{R_R U_{MIN} + R_F U_{MAX}}{R_R + R_F}$$

- 15 8. The process control apparatus (100) of claim 5 wherein the apparatus (100) is configured for controlling a self-regulated process in which the process model parameters include a time constant T_C , a static process gain K_S , and a process dead time L and wherein the estimating means (126) comprises:

20 means for calculating a rising time constant T_R , a rising static process gain K_R , a falling time constant T_F and a falling static gain K_F according to the mathematical expressions:

$$25 \quad \begin{bmatrix} T_R \\ K_R \end{bmatrix} = \frac{1}{U_{MAX} (N \sum R_{Rn}^2 - (\sum R_{Rn})^2)} \begin{bmatrix} -NU_{MAX} \sum y_n R_{Rn} + U_{MAX} (\sum R_{Rn}) (\sum y_n) \\ (-\sum R_{Rn}) (\sum R_{Rn} y_n) + (\sum R_{Rn}^2) (\sum y_n) \end{bmatrix}$$

$$30 \quad \begin{bmatrix} T_F \\ K_F \end{bmatrix} = \frac{1}{U_{MIN} (N \sum R_{Fn}^2 - (\sum R_{Fn})^2)} \begin{bmatrix} -NU_{MIN} \sum y_n R_{Fn} + U_{MIN} (\sum R_{Fn}) (\sum y_n) \\ (-\sum R_{Fn}) (\sum R_{Fn} y_n) + (\sum R_{Fn}^2) (\sum y_n) \end{bmatrix}$$

35 where N is a number of samples of the measured process variable (y(t)) in the rising and falling directions, n ranges from 1 to N, R_{Rn} is the rising rate-of-change of the measured process variable (y(t)) at the nth sample, y_n is the measured process variable (y(t)) at the nth sample and R_{Fn} is the falling rate-of-change of the measured process variable (y(t)) at the nth sample; and means for estimating T_C as a minimum of T_R and T_F and estimating K_S as a maximum of K_R and K_F .

- 40 9. The process control apparatus (100) of claim 8 wherein the estimating means (126) further comprises:

45 means for calculating a rising process dead time L_R and a falling process dead time L_F according to the mathematical expressions:

$$46 \quad L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_{R1}}$$

$$47 \quad L_F = t_{MAX} - t_F - \frac{y(t_{MAX}) - y_{MAX}}{R_{F1}}$$

50 where t_{MAX} and t_{MAX} are times at which the measured process variable (y(t)) is maximally increasing and decreasing, respectively, t_R and t_F are times at which U_{MAX} and U_{MIN} are applied to the excitation output, respectively, $y(t_{MAX})$ and $y(t_{MAX})$ are the measured process variable (y(t)) at times t_{MAX} and t_{MAX} , respectively, y_{MIN} is the minimum measured process variable (y(t)) between times t_R and t_F , y_{MAX} is the maximum measured process variable (y(t)) between times t_F and t_A , where t_A is a time at which U_{MIN} is removed, and R_{R1} and R_{F1} are the rising and falling rates-of-change of the measured process variable (y(t)) at sample n=1, respectively; and

55 means for estimating L as a maximum of L_R and L_F .

10. A method of determining tuning parameters for a process control system (100) which controls a process (110) through a control output signal ($u(t)$) as a function of a measured process variable ($y(t)$) and a set point (y_{SET}), the method comprising:

varying the control output signal ($u(t)$) over time such that the measured process variable rises and falls;
 5 **characterized by:**

determining a rising dead time L_R in the measured process variable ($y(t)$);
 determining a rising rate-of-change R_R in the measured process variable ($y(t)$);
 10 determining a falling dead time L_F in the measured process variable ($y(t)$);
 determining a falling rate-of-change R_F in the measured process variable ($y(t)$); and
 tuning the function of the process control system (100) based on L_R , L_F , R_R and R_F .

Patentansprüche

1. Prozeßsteuerungsvorrichtung (100) zum Steuern eines Prozesses (110) durch ein Steuerungsausgangssignal ($u(t)$) als Funktion einer gemessenen Prozeßgröße ($y(t)$) mit:

einer Steuerungseinrichtung (104) mit einem Prozeßgrößeneingang und einem Steuerausgang, wobei die Steuerungseinrichtung das Steuerungsausgangssignal ($u(t)$) am Steuerausgang in Antwort auf die am Prozeßgrößeneingang gemessene Prozeßgröße ($y(t)$) und basierend auf Steuerfunktionsparametern erzeugt; und

einer Abstimmungseinrichtung (106) mit:

einer Anregungseinrichtung (124) mit einem mit dem Steuerausgang gekoppelten Anregungsausgang zum Erzeugen eines Anregungssignals, das mit der Zeit ansteigt und abfällt;

dadurch gekennzeichnet, daß
 die Abstimmungseinrichtung (106) ferner aufweist:

eine Abschätzeinrichtung (126) zum Berechnen einer Anstiegs-Totzeit L_R , einer Abfall-Totzeit L_F , einer Anstiegs-Änderungsrate R_R und einer Abfall-Änderungsrate R_F in der gemessenen Prozeßgröße ($y(t)$) in Antwort auf das Anregungssignal und zum Bestimmen eines Prozeßmodells basierend auf L_R , L_F , R_R und R_F ; und
 eine mit der Abschätzeinrichtung (126) gekoppelte ParameterAbschätzeinrichtung (128) zum Berechnen der Steuerfunktionsparameter basierend auf dem Prozeßmodell.

2. Prozeßsteuerungsvorrichtung (100) nach Anspruch 1, wobei die Abschätzeinrichtung (126) eine Einrichtung zum Berechnen von R_R und R_F gemäß den mathematischen Ausdrücken

$$R_R = \frac{\sum_{n=1}^N R_{Rn}}{N}$$

$$R_F = \frac{\sum_{n=1}^N R_{Fn}}{N}$$

aufweist, wobei N eine ausgewählte Anzahl von Abtastwerten der gemessenen Prozeßgröße ($y(t)$) in der Anstiegs- und in der Abfallrichtung und R_{Rn} und R_{Fn} die Anstiegs- und Abfall-Änderungsraten der gemessenen Prozeßgröße ($y(t)$) am n -ten Abtastwert bezeichnen.

3. Prozeßsteuerungsvorrichtung (100) nach Anspruch 1 oder 2, wobei die Abschätzeinrichtung (126) aufweist:

eine Einrichtung zum Inkrementieren des Anregungsausgangssignals ausgehend von einem ausgewählten Minimalwert U_{MIN} zu einem ausgewählten Maximalwert U_{MAX} und zum Dekrementieren des Anregungssignals von U_{MAX} zu U_{MIN} ; und
 eine Einrichtung zum Berechnen von L_R und L_F gemäß den mathematischen Ausdrücken:

$$L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_R}$$

$$L_F = t_{MAX} - t_F - \frac{y(t_{MAX}) - y_{MAX}}{-R_F}$$

wobei t_{MAX} und t_{MIN} Zeitpunkte sind, an denen die gemessene Prozeßgröße ($y(t)$) maximal ansteigt bzw. abfällt, t_R und t_F Zeitpunkte sind, an denen U_{MAX} bzw. U_{MIN} dem Anregungsausgang zugeführt wird, $y(t_{MAX})$ und $y(t_{MIN})$ Werte der gemessenen Prozeßgröße ($y(t)$) zu Zeitpunkten t_{MAX} bzw. t_{MIN} sind, y_{MIN} die zwischen den Zeitpunkten t_R und t_F gemessene minimale Prozeßgröße ist, und y_{MAX} die zwischen den Zeitpunkten t_F und t_A gemessene maximale Prozeßgröße ist, wobei t_A einen Zeitpunkt bezeichnet, an dem U_{MIN} entfernt wird.

4. Prozeßsteuerungsvorrichtung (100) nach einem der Ansprüche 1 bis 3, wobei das Prozeßmodell einen Prozeßtotzeitwert L aufweist und die Abschätzeinrichtung (126) L als Maximum von L_R und L_F bestimmt.

5. Prozeßsteuerungsvorrichtung (100) nach einem der Ansprüche 1 bis 4, wobei die Anregungseinrichtung (124) aufweist:

eine Einrichtung zum Inkrementieren des Anregungssignals ausgehend von einem ausgewählten Minimalwert U_{MIN} zu einem ausgewählten Maximalwert U_{MAX} und zum Dekrementieren des Anregungssignals von U_{MAX} zu U_{MIN} .

6. Prozeßsteuerungsvorrichtung (100) nach Anspruch 5, wobei die Vorrichtung (100) zum Steuern eines nichtselbstregelnden Prozesses konfiguriert ist, in dem die Prozeßmodellparameter eine Konstante m_1 aufweisen, und die Abschätzeinrichtung (126) eine Einrichtung zum Bestimmen von m_1 gemäß dem mathematischen Ausdruck

$$m_1 = \frac{R_R + R_F}{U_{MAX} - U_{MIN}}$$

aufweist.

7. Prozeßsteuerungsvorrichtung (100) nach Anspruch 5, wobei die Vorrichtung (100) zum Steuern eines nichtselbstregelnden Prozesses konfiguriert ist, in dem die Prozeßmodellparameter einen berechneten Beharrungszustandswert U_{EST} des Steuerungsausgangssignals aufweisen, und die Abschätzeinrichtung (126) eine Einrichtung zum Bestimmen von U_{EST} gemäß dem mathematischen Ausdruck

$$U_{EST} = \frac{R_R U_{MIN} + R_F U_{MAX}}{R_R + R_F}$$

aufweist.

8. Prozeßsteuerungsvorrichtung (100) nach Anspruch 5, wobei die Vorrichtung (100) zum Steuern eines selbstregelnden Prozesses konfiguriert ist, in dem die Prozeßmodellparameter eine Zeitkonstante T_C , einen statischen Prozeßverstärkungsfaktor K_S und eine Prozeßtotzeit L aufweisen, und wobei die Abschätzeinrichtung (126) aufweist:

eine Einrichtung zum Berechnen einer Anstiegs-Zeitkonstanten T_R , eines statischen Anstiegs-Verstärkungsfaktors K_R , einer Abfall-Zeitkonstanten T_F und eines statischen Abfall-Verstärkungsfaktors K_F gemäß den mathematischen Ausdrücken:

$$\begin{bmatrix} T_R \\ K_R \end{bmatrix} = \frac{1}{U_{MAX}(N \sum R_{Rn}^2 - (\sum R_{Rn})^2)} \begin{bmatrix} -NU_{MAX} \sum y_n R_{Rn} + U_{MAX}(\sum R_{Rn})(\sum y_n) \\ (-\sum R_{Rn})(\sum R_{Rn} y_n) + (\sum R_{Rn}^2)(\sum y_n) \end{bmatrix}$$

$$\begin{bmatrix} T_F \\ K_F \end{bmatrix} = \frac{1}{U_{MIN}(N \sum R_{Fn}^2 - (\sum R_{Fn})^2)} \begin{bmatrix} -NU_{MIN} \sum y_n R_{Fn} + U_{MIN}(\sum R_{Fn})(\sum y_n) \\ (-\sum R_{Fn})(\sum R_{Fn} y_n) + (\sum R_{Fn}^2)(\sum y_n) \end{bmatrix}$$

wobei N die Anzahl von Abtastwerten der gemessenen Prozeßgröße (y(t)) in der Anstiegs- und in der Abfallrichtung ist, n im Bereich von 1 bis N liegt, R_{Rn} die Anstiegs-Änderungsrate der gemessenen Prozeßgröße (y(t)) am n-ten Abtastwert, y_n die gemessene Prozeßgröße (y(t)) am n-ten Abtastwert und R_{Fn} die Abfall-Änderungsrate der gemessenen Prozeßgröße (y(t)) am n-ten Abtastwert bezeichnen; und eine Einrichtung zum Bestimmen von T_C als Minimum von T_R und T_F und zum Bestimmen von K_S als Maximum von K_R und K_F .

9. Prozeßsteuerungsvorrichtung (100) nach Anspruch 8, wobei die Abschätzeinrichtung (126) ferner aufweist:

eine Einrichtung zum Berechnen einer Anstiegs-Prozeßtotzeit L_R und einer Abfall-Prozeßtotzeit L_F gemäß den mathematischen Ausdrücken:

$$L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_{R1}}$$

$$L_F = t_{MAX} - t_F - \frac{y(t_{MAX}) - y_{MAX}}{R_{F1}}$$

wobei t_{MAX} und t_{MAX} Zeitpunkte bezeichnen, an denen die gemessene Prozeßgröße (y(t)) maximal ansteigt bzw. abfällt, t_R und t_F Zeitpunkte bezeichnen, an denen U_{MAX} bzw. U_{MIN} dem Anregungsausgang zugeführt wird, $y(t_{MAX})$ und $y(t_{MAX})$ die gemessene Prozeßgröße (y(t)) zu Zeitpunkten t_{MAX} bzw. t_{MAX} bezeichnen, y_{MIN} die zwischen Zeitpunkten t_R und t_F gemessene minimale Prozeßgröße (y(t)), y_{MAX} die zwischen Zeitpunkten t_F und t_A gemessene maximale Prozeßgröße (y(t)), wobei t_A einen Zeitpunkt bezeichnet, an dem U_{MIN} entfernt wird, und R_{R1} und R_{F1} die Anstiegs- bzw. die Abfall-Änderungsrate der gemessenen Prozeßgröße (y(t)) am Abtastwert $n = 1$ bezeichnen; und eine Einrichtung zum Bestimmen von L als Maximum von L_R und L_F .

10. Verfahren zum Bestimmen von Abstimmungsparametern für ein Prozeßsteuerungssystem (100), das einen Prozeß (110) durch ein Steuerungsausgangssignal (u(t)) als Funktion einer gemessenen Prozeßgröße (y(t)) und eines Sollwertes (Y_{SET}) steuert, wobei das Verfahren aufweist:

Verändern des Steuerungsausgangssignals (u(t)) mit der Zeit, so daß die gemessene Prozeßgröße ansteigt und abfällt;

gekennzeichnet durch:

Bestimmen einer Anstiegs-Totzeit L_R in der gemessenen Prozeßgröße (y(t));
Bestimmen einer Anstiegs-Änderungsrate R_R in der gemessenen Prozeßgröße (y(t));
Bestimmen einer Abfall-Totzeit L_F in der gemessenen Prozeßgröße (y(t));
Bestimmen einer Abfall-Änderungsrate R_F in der gemessenen Prozeßgröße (y(t)); und

Abstimmen der Funktion des Prozeßsteuerungssystems (100) basierend auf L_R , L_F , R_R und R_F .

Revendications

- 5
1. Dispositif de commande de processus (100) destiné à commander un processus (110) par l'intermédiaire d'un signal de sortie de commande ($u(t)$) en fonction d'une variable de processus mesurée ($y(t)$), comprenant :
- 10 un moyen de commande (104) comportant une entrée de variable de processus et une sortie de commande, dans lequel le moyen de commande génère le signal de sortie de commande ($u(t)$) sur la sortie de commande en réponse à la variable de processus mesurée ($y(t)$) reçue sur l'entrée de variable de processus et sur la base des paramètres d'une fonction de commande, et un moyen d'accord (106) comprenant :
- 15 un moyen d'excitation (124) comportant une sortie d'excitation reliée à la sortie de commande en vue de générer un signal d'excitation qui monte et descend au cours du temps, caractérisé en ce que le moyen d'accord (106) comprend en outre :
- 20 un moyen d'estimation (126) destiné à calculer un temps mort de montée L_R , un temps mort de descente L_F , une vitesse de variation de montée R_R et une vitesse de variation de descente R_F dans la variable de processus mesurée ($y(t)$) en réponse au signal d'excitation et destiné à estimer une modélisation du processus sur la base des valeurs L_R , L_F , R_R et R_F , et un moyen de calcul de paramètres (128) relié au moyen d'estimation (126) afin de calculer des paramètres de la fonction de commande sur la base de la modélisation du processus.
- 26 2. Dispositif de commande de processus (100) selon la revendication 1, dans lequel le moyen d'estimation (126) comprend un moyen destiné à calculer R_R et R_F conformément aux expressions mathématiques:

30

$$R_R = \frac{\sum_{n=1}^N R_{Rn}}{N}$$

36

$$R_F = \frac{\sum_{n=1}^N R_{Fn}}{N}$$

40 où N est un nombre choisi d'échantillons de la variable de processus mesurée ($y(t)$) dans les sens de montée et de descente et R_{Rn} et R_{Fn} sont les vitesses de variations de montée et de descente de la variable de processus mesurée ($y(t)$) pour le $n^{\text{ième}}$ échantillonnage.

- 45 3. Dispositif de commande de processus (100) selon la revendication 1 ou 2, dans lequel le moyen d'estimation (126) comprend :

un moyen destiné à incrémenter le signal de sortie d'excitation depuis une valeur minimum sélectionnée U_{MIN} jusqu'à une valeur maximum sélectionnée U_{MAX} et destiné à décrémenter le signal d'excitation de U_{MAX} vers U_{MIN} , et

50 un moyen destiné à calculer L_R et L_F conformément aux expressions mathématiques :

55

$$L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_R}$$

$$L_F = t_{-MAX} - t_F - \frac{y(t_{-MAX}) - y_{MAX}}{R_F}$$

où t_{MAX} et t_{MIN} sont des instants auxquels la variable de processus mesurée ($y(t)$) augmente et diminue de façon maximale, respectivement, t_R et t_F sont des instants auxquels U_{MAX} et U_{MIN} sont appliquées à la sortie d'excitation, respectivement, $y(t_{MAX})$ et $y(t_{MIN})$ sont des valeurs de la variable de processus mesurée ($y(t)$) aux instants t_{MAX} et t_{MIN} , respectivement, y_{MIN} est la variable de processus mesurée minimum entre les instants t_R et t_F , et y_{MAX} est la variable de processus mesurée maximum entre les instants t_F et t_A , où t_A est un instant auquel U_{MIN} est supprimée.

4. Dispositif de commande de processus (100) selon l'une quelconque des revendications 1 à 3, dans lequel la modélisation de processus comprend une valeur de temps mort de processus L et le moyen d'estimation (126) estime L sous forme du maximum de L_R et L_F .
5. Dispositif de commande de processus (100) selon l'une quelconque des revendications 1 à 4, dans lequel le moyen d'excitation (124) comprend :
un moyen destiné à incrémenter le signal d'excitation depuis une valeur minimum sélectionnée U_{MIN} jusqu'à une valeur maximum U_{MAX} et destiné à décrémenter le signal d'excitation de U_{MAX} vers U_{MIN} .
6. Dispositif de commande de processus (100) selon la revendication 5, dans lequel le dispositif (100) est configuré de façon à commander un processus qui n'est pas auto-régulé dans lequel les paramètres de modélisation du processus comprennent une constante m_1 , et le moyen d'estimation (126) comprend un moyen destiné à estimer m_1 conformément à l'expression mathématique :

$$m_1 = \frac{R_R + R_F}{U_{MAX} - U_{MIN}}$$

7. Dispositif de commande de processus (100) selon la revendication 5, dans lequel le dispositif (100) est configuré pour commander un processus qui n'est pas auto-régulé dans lequel les paramètres de modélisation du processus comprennent une valeur d'état stable estimée U_{EST} du signal de sortie de commande et le moyen d'estimation (126) comprend un moyen destiné à estimer U_{EST} conformément à l'expression mathématique :

$$U_{EST} = \frac{R_R U_{MIN} + R_F U_{MAX}}{R_R + R_F}$$

8. Dispositif de commande de processus (100) selon la revendication 5, dans lequel le dispositif (100) est configuré en vue de commander un processus auto-régulé dans lequel les paramètres de modélisation du processus comprennent une constante de temps T_C , un gain de processus statique K_S , et un temps mort de processus L et dans lequel le moyen d'estimation (126) comprend :

un moyen destiné à calculer une constante de temps de montée T_R , un gain de processus statique de montée K_R , une constante de temps de descente T_F et un gain statique de descente K_F conformément aux expressions mathématiques.

$$\begin{bmatrix} T_R \\ K_R \end{bmatrix} = \frac{1}{U_{MAX} (N \sum R_{Rn}^2 - (\sum R_{Rn})^2)} \begin{bmatrix} -NU_{MAX} \sum y_n R_{Rn} + U_{MAX} (\sum R_{Rn}) (\sum y_n) \\ (-\sum R_{Rn}) (\sum R_{Rn} y_n) + (\sum R_{Rn}^2) (\sum y_n) \end{bmatrix}$$

$$\begin{bmatrix} T_F \\ K_F \end{bmatrix} = \frac{1}{U_{MIN} (N \sum R_{Fn}^2 - (\sum R_{Fn})^2)} \begin{bmatrix} -NU_{MIN} \sum y_n R_{Fn} + U_{MIN} (\sum R_{Fn}) (\sum y_n) \\ (-\sum R_{Fn}) (\sum R_{Fn} y_n) + (\sum R_{Fn}^2) (\sum y_n) \end{bmatrix}$$

où N est un certain nombre d'échantillonnages de la variable de processus mesurée ($y(t)$) dans les sens de montée et de descente, n va de 1 à N, R_{Rn} est la vitesse de variation de montée de la variable de processus mesurée ($y(t)$) au n^{ième} échantillonnage, y_n est la variable de processus mesurée ($y(t)$) au n^{ième} échantillonnage.

nage et R_{Fn} est la vitesse de variation de descente de la variable de processus mesurée ($y(t)$) au $n^{\text{ième}}$ échantillonnage, et
 un moyen destiné à estimer T_C sous forme d'un minimum de T_R et T_F et à estimer K_S sous forme d'un maximum de K_R et K_F .

- 5
 9. Dispositif de commande de processus (100) selon la revendication 8, dans lequel le moyen d'estimation (126) comprend en outre :

10 un moyen destiné à calculer un temps mort de processus de montée L_R et un temps mort de processus de descente L_F conformément aux expressions mathématiques :

$$L_R = t_{MAX} - t_R - \frac{y(t_{MAX}) - y_{MIN}}{R_{R1}}$$

$$L_F = t_{MAX} - t_F - \frac{y(t_{MAX}) - y_{MAX}}{R_{F1}}$$

20 où t_{MAX} et t_{MAX} sont des instants auxquels la variable de processus mesurée ($y(t)$) augmente et diminue de façon maximale, respectivement, t_R et t_F sont des instants auxquels U_{MAX} et U_{MIN} sont appliqués à la sortie d'excitation, respectivement, $y(t_{MAX})$ et $y(t_{MAX})$ sont les valeurs de la variable de processus mesurée ($y(t)$) aux instants t_{MAX} et t_{MAX} , respectivement, y_{MIN} est la variable de processus mesurée minimum ($y(t)$) entre les instants t_R et t_F , y_{MAX} est la variable de processus mesurée maximum ($y(t)$) entre les instants t_F et t_A , où
 25 t_A est un instant auquel U_{MIN} est supprimé, et R_{R1} et R_{F1} sont les vitesses de variation de montée et de descente de la variable de processus mesurée ($y(t)$) à l'échantillonnage $n=1$, respectivement, et un moyen destiné à estimer L en tant que maximum de L_R et L_F .

- 30 10. Procédé de détermination des paramètres d'accord pour un système de commande de processus (100) qui commande un processus (110) par l'intermédiaire d'un signal de sortie de commande ($u(t)$) en fonction d'une variable de processus mesurée ($y(t)$) et un point de consigne (y_{SET}), le procédé comprenant :

le fait de faire varier le signal de sortie de commande ($u(t)$) par rapport au temps de telle manière que la variable de processus mesurée monte et descende, caractérisé par :

35 la détermination d'un temps mort de montée L_R dans la variable de processus mesurée ($y(t)$),
 la détermination d'une vitesse de variation de montée R_R dans la variable de processus mesurée ($y(t)$),
 la détermination d'un temps mort de descente L_F dans la variable de processus mesurée ($y(t)$),
 la détermination d'une vitesse de variation de descente R_F dans la variable de processus mesurée ($y(t)$), et
 40 l'accord de la fonction du système de commande de processus (100) sur la base de L_R , L_F , R_R et R_F .
